HYDROXAMIC ACID SUBSTITUTED FUSED
HETEROCYCLIC METALLOPROTEINASE INHIBITORS

5

BACKGROUND OF THE INVENTION

This application claims the benefit of U.S. Provisional Application No. 60/054,753 filed August 4, 1997, which is hereby incorporated by reference. The present invention relates to metalloproteinase inhibitors and more particularly, relates to novel compounds, composition and method for prophylaxis and treatment of inflammation, tissue degradation and the like. This invention, in particular, relates to novel hydroxamic acid substituted fused heterocyclic compounds, compositions containing such compounds and methods of use of such compounds. The subject invention also relates to processes for making such compounds as well as to intermediates useful in such processes.

20 Metalloproteinase enzymes, such as collagenases (e.g., MMP-1, MMP-8 and MMP-13), stromelysins (e.g., MMP-3, MMP-10, MMP-11 and MMP-7), gelatinases (e.g., MMP-2 and MMP-9) and TNF convertase, may contribute to the onset, etiology, or exacerbate disease states which are related to connective tissue degradation, secretion of proinflammatory cytokines and the like. For example, matrix metalloproteinases, such as collagenases, stromelysins and gelatinases, are thought to be involved in the tissue breakdown observed in rheumatoid arthritis; osteoarthritis; osteopenias (e.g., osteoporosis); periodontitis; gingivitis; corneal, epidermal and gastric ulceration; and tumour metastasis, invasion and growth; in neuroinflammatory disorders, such as myelin degradation (e.g., multiple sclerosis); and in angiogenesis dependent diseases, such as arthritic conditions; solid tumor growth; psoriasis;

proliferative retinopathies; neovascular glaucoma; ocular tumours; angiofibromas; and hemangiomas.

Tumor Necrosis Factor alpha (TNF- α) is a proinflammatory cytokine secreted by a variety of cells including monocytes and macrophages in response to many inflammatory stimuli (e.g. lipopolysaccharide - LPS) or external cellular stress (e.g. osmotic shock, peroxide). Elevated levels of TNF play a major role in mediating many inflammatory disease states. Elevated levels of TNF- α may contribute to the onset, etiology, or exacerbate the following disease states: rheumatoid arthritis; osteoarthritis; rheumatoid spondylitis; gouty arthritis; inflammatory bowel disease; adult respiratory distress syndrome (ARDS); psoriasis; Crohn's disease; allergic rhinitis; ulcerative colitis; anaphylaxis; contact dermatitis; asthma; antiviral therapy including those viruses sensitive to TNF- α inhibition - HIV-1, HIV-2, HIV-3, cytomegalovirus (CMV), influenza, adenovirus, and the herpes viruses including HSV-1, HSV-2, and herpes zoster; muscle degeneration; cachexia; Reiter's syndrome; type II diabetes; bone resorption diseases; graft vs. host reaction; ischemia reperfusion injury; atherosclerosis; brain trauma; Alzheimer's disease; multiple sclerosis; cerebral malaria; sepsis; septic shock; toxic shock syndrome; fever and myalgias due to infection.

Several approaches have been taken to block the effects of TNF- α . One approach involves utilizing soluble receptors for TNF- α (e.g., TNFR-55 or TNFR-75) which have demonstrated efficacy in animal models of TNF- α mediated disease states. A second approach to neutralizing TNF- α utilizing a monoclonal antibody specific to TNF- α , cA2, has demonstrated improvement in swollen joint count in a Phase II human trial of rheumatoid arthritis (Feldmann et al Immunological Reviews p.195-223 (1995)).

The above approaches block the effects of TNF- α by either protein sequesterazation or receptor antagonism, but an additional approach to blockade is to intervene in the cellular secretion of TNF. TNF convertase is
5 thought to be a metalloproteinase enzyme involved in the cellular secretion of TNF- α (Mohler et al., Nature 370:218-220, 1994; Gearing et al., Nature 370:555-557, 1994; McGeehan et al., Nature 370:558-561, 1994). Inhibition of TNF convertase is thought to be an
10 additional approach to intervene in the cellular secretion of TNF- α . For example, a metalloproteinase inhibitor was shown to inhibit cellular secretion of TNF- α , in vitro and in vivo, which was thought to be due to inhibition of TNF convertase (McGeehan et al., Nature
15 370:558-561, 1994). WO 92/02822, WO 94/00555, WO 95/24501, WO 96/41624, WO 98/02557 and US Pat. 5,594,106 (each of which is incorporated herein by reference in its entirety) describe a TNF- α convertase and methods of identifying inhibitors thereof. While evidence as to
20 the nature of intervention by metalloproteinase inhibitors in the cellular secretion of TNF- α exists, additional or alternative mechanisms of action by which such compounds inhibit TNF secretion may be involved, such as by intervening at a point on the pathway between
25 extracellular stimulus and secretion of protein.

Since TNF- α is upstream in the cytokine cascade of inflammation wherein elevated levels of TNF- α lead to elevated levels of other cytokines including IL-1, IL-6 and IL-8, inhibiting the secretion of TNF- α may also
30 reduce levels of other cytokines including but not limited to IL-1, IL-6 or IL-8.

Further, TNF- α is thought to play a role in head trauma, stroke, and ischemia. For instance, in animal models of head trauma (rat), TNF- α levels increased in
35 the contused hemisphere (Shohami et al J. Cereb. Blood

Flow Metab. 14:615-619 (1994)). In an model of ischemia wherein the middle cerebral artery was occluded in rats, the levels of mRNA of TNF- α increased (Feurstein et al Neurosci. Lett. 164:125-128 (1993)). Administration of

5 TNF- α into the rat cortex resulted in significant PMN accumulation in capillaries and adherence in small blood vessels. TNF- α promotes the infiltration of other cytokines (IL-1b, IL-6), and also chemokines, which promote neutrophil infiltration into the infarct area

10 (Feurstein Stroke 25:1481-1488 (1994)).

TNF- α may also play a role in promoting certain viral life cycles and disease states associated with them. For instance, TNF- α secreted by monocytes induced elevated levels of HIV expression in a chronically

15 infected T cell clone (Clouse et al, J. Immunol. 142:431 (1989)). The role of TNF- α in the HIV associated states of cachexia and muscle degradation has been discussed (Lahdevirta et al The American J. Med. 85:289 (1988)).

10 "Leaving group" generally refers to groups readily displaceable by a nucleophile, such as an amine, a thiol or an alcohol nucleophile. Such leaving groups are well known in the art. Examples of such leaving groups
include, but are not limited to, N-hydroxysuccinimide,
15 N-hydroxybenzotriazole, halides, triflates, tosylates and the like. Preferred leaving groups are indicated herein where appropriate.

"Protecting group" generally refers to groups well known
20 in the art which are used to prevent selected reactive groups, such as carboxy, amino, hydroxy, mercapto and the like, from undergoing undesired reactions, such as nucleophilic, electrophilic, oxidation, reduction and the like. Preferred protecting groups are indicated
25 herein where appropriate. Examples of amino protecting groups include, but are not limited to, aralkyl, substituted aralkyl, cycloalkenylalkyl and substituted cycloalkenyl alkyl, allyl, substituted allyl, acyl, alkoxycarbonyl, aralkoxycarbonyl, silyl and the like.
30 Examples of aralkyl include, but are not limited to, benzyl, ortho-methylbenzyl, trityl and benzhydryl, which can be optionally substituted with halogen, alkyl, alkoxy, hydroxy, nitro, acylamino, acyl and the like, and salts, such as phosphonium and ammonium salts.
35 Examples of aryl groups include phenyl, naphthyl, indanyl, anthracenyl, 9-(9-phenylfluorenyl), phenanthrenyl, durenyl and the like. Examples of

Suitable acyl, alkoxycarbonyl and aralkoxy-carbonyl groups include benzyloxycarbonyl, t-butoxycarbonyl, iso-butoxycarbonyl, benzoyl, substituted benzoyl, butyryl, acetyl, tri-fluoroacetyl, tri-chloro acetyl, phthaloyl and the like. A mixture of protecting groups can be used to protect the same amino group, such as a primary amino group can be protected by both an aralkyl group and an aralkoxycarbonyl group. Amino protecting groups can also form a heterocyclic ring with the nitrogen to which they are attached, for example, 1,2-bis(methylene)benzene, phthalimidyl, succinimidyl, maleimidyl and the like and where these heterocyclic groups can further include adjoining aryl and cycloalkyl rings. In addition, the heterocyclic groups can be mono-, di- or tri-substituted, such as nitrophthalimidyl. Amino groups may also be protected against undesired reactions, such as oxidation, through the formation of an addition salt, such as hydrochloride, toluenesulfonic acid, trifluoroacetic acid and the like. Many of the amino protecting groups are also suitable for protecting carboxy, hydroxy and mercapto groups. For example, aralkyl groups. Alkyl groups are also suitable groups for protecting hydroxy and mercapto groups, such as tert-butyl.

Silyl protecting groups are silicon atoms optionally substituted by one or more alkyl, aryl and aralkyl groups. Suitable silyl protecting groups include, but are not limited to, trimethylsilyl, triethylsilyl, tri-isopropylsilyl, tert-butyldimethylsilyl, dimethylphenylsilyl, 1,2-bis(dimethylsilyl)-benzene, 1,2-bis(dimethylsilyl)ethane and diphenylmethylsilyl. Silylation of an amino groups provide mono- or di-silylamino groups. Silylation of amino-alcohol compounds can lead to a N,N,O-tri-silyl

derivative. Removal of the silyl function from a silyl ether function is readily accomplished by treatment with, for example, a metal hydroxide or ammonium flouride reagent, either as a discrete reaction step or
5 in situ during a reaction with the alcohol group. Suitable silylating agents are, for example, trimethylsilyl chloride, tert-butyldimethylsilyl chloride, phenyldimethylsilyl chloride, diphenylmethyl silyl chloride or their combination products with imidazole or
10 DMF. Methods for silylation of amines and removal of silyl protecting groups are well known to those skilled in the art. Methods of preparation of these amine derivatives from corresponding amino acids, amino acid amides or amino acid esters are also well known to those
15 skilled in the art of organic chemistry including amino acid/amino acid ester or aminoalcohol chemistry.

Protecting groups are removed under conditions which will not affect the remaining portion of the molecule. These methods are well known in the art and
20 include acid hydrolysis, hydrogenolysis and the like. A preferred method involves removal of a protecting group, such as removal of a benzyloxycarbonyl group by hydrogenolysis utilizing palladium on carbon in a suitable solvent system such as an alcohol, acetic acid,
25 and the like or mixtures thereof. A t-butoxycarbonyl protecting group can be removed utilizing an inorganic or organic acid, such as HCl or trifluoroacetic acid, in a suitable solvent system, such as dioxane or methylene chloride. The resulting amino salt can readily be
30 neutralized to yield the free amine. Carboxy protecting group, such as methyl, ethyl, benzyl, tert-butyl, 4-methoxyphenylmethyl and the like, can be removed under hydrolysis and hydrogenolysis conditions well known to those skilled in the art.

Procedures for preparing the compounds of this invention are set forth below. It should be noted that the general procedures are shown as it relates to preparation of compounds having unspecified stereochemistry. However, such procedures are generally applicable to those compounds of a specific stereochemistry, e.g., where the stereochemistry about a group is (S) or (R). In addition, the compounds having one stereochemistry (e.g., (R)) can often be utilized to produce those having opposite stereochemistry (i.e., (S)) using well-known methods, for example, by inversion.

Preparation of Compounds of Formula I

The compounds of the present invention represented by Formula I above can be prepared utilizing the following general procedures as schematically shown in Schemes I and II.

Compounds of the present invention may be synthesised using the routes outlined in Schemes I

through IV. An appropriately substituted protected (for example, P_1 is a methyl, ethyl, benzyl and the like) or unprotected (P_1 is H) amino acid (1) upon treatment with appropriately functionalized aldehydes or ketones (2) under acidic conditions (for example see Sola, R. et al, J. Heterocycles, 19, 1982), can give the bicyclic intermediate (3). The acid functionality of the bicyclic intermediate (3) (when P_1 is H) is then be converted into an ester using standard procedures (for example HCl and methanol). The protected bicyclic intermediate (3) is then sulfonylated under Schotten-Baumann conditions to furnish the sulfonamide (4). Sulfonamide (4) (when R^9 is H) may be halogenated, such as iodinated, and then carbonylated (See for example Schoenberg, A., et al, J.Org.Chem., 39, 3318, (1974)) and subsequently derivatised, amidated (See for example Corey, E.J. and Hegedus, L.S., J.Am.Chem.Soc., 91, 1233 (1969)), arylated or alkylated (See for example Stille, J.K., Angew. Int. Ed. Engl., 25, 508 (1986)) to yield sulfonamide (4) where R^9 is other than H. Sulfonamide (4) can be readily converted into the corresponding hydroxamic acids (5) using procedures well known to those skilled in the art. Alternatively, R^{11} and/or R^{12} may be introduced into sulfonamide (4), where R^{11} and/or R^{12} are independently a leaving group (L' and L'' , respectively) utilizing suitably functionalized nucleophilic species (such as $R^{21}SH$ or $R^{33}NH_2$, followed by reaction with the electrophile $R^{31}N=C=O$, $R^{32}R^{31}N-C(O)-L$, $R^{31}-C(O)-L$, $R^{30}-SO_2-L$, $R^{32}R^{31}N-SO_2-L$, and the like) and/or a hydroxy, amino, substituted amino or thiol group utilizing suitably functionalized electrophilic species (such as $R^{31}N=C=O$, $R^{32}R^{31}N-C(O)-L$, $R^{20}-L$, $R^{22}-C(O)-L$ and the like), where L , L' and L'' are each a leaving group, such as chloro, bromo, iodo, mesylate, tosylate and the like. When R^{11} or R^{12} is a hydroxy, amino, substituted amino or thiol group, the groups may require selective protection and de-protection, using reagents and methods well known

in the art, in order to avoid producing undesired reaction products.

SCHEME II

Alternatively, an appropriately substituted heterocyclic carboxaldehyde (6) (Scheme II) may be condensed, under basic conditions, with a glycine to give the hydroxy amino acid (7) (See for example Dullaghan, M.E. and Nord, F.F., J.Am.Chem.Soc., 73, 5455 (1951)). The hydroxy amino acid (7) is then protected (for example, esterified) to yield the protected amino acid (8). Cyclization of the protected amino acid (8) under acidic conditions with an appropriately

functionalized aldehyde or ketone (2) can furnish the bicyclic intermediate (9). Sulfonylation, using Schotten-Baumann conditions, of the bicyclic intermediate (9) can give the sulfonamide (10a).

- 5 Sulfonamide (10a) can be readily converted into the corresponding hydroxamic acid (11), where R^{11} is -OH, using procedures well known to those skilled in the art. Alternatively, sulfonamide (10a) may be derivatized by treatment with a suitably functionalized electrophilic species, such as $R^{31}N=C=O$, $R^{32}R^{31}N-C(O)-L$, $R^{20}-L$, $R^{22}-C(O)-L$ and the like, where L is a leaving group, such as chloro, bromo, iodo, mesylate, tosylate and the like, to generate sulfonamide (10b). (See for example Duggan, M.E. and Imagrre J.S., Synthesis 131 (1989)).
- 15 Sulfonamide (10b) can be readily converted into the corresponding hydroxamic acid (11) using procedures well known to those skilled in the art. Alternatively, the hydroxy group of sulfonamide (10a) may be converted into a leaving group ($R^a = L$) by treatment with a suitable agents well known to those skilled in the art, such as halogenating agents (for example PCl_5 , PBr_3 , and the like), mesyl chloride, tosyl chloride, and the like, where L is a leaving group, such as chloro, bromo, iodo, mesylate, tosylate and the like, to generate sulfonamide (10c). The leaving group (L) of sulfonamide (10c) can be displaced with a nucleophile, such as $R^{21}SH$ or $R^{33}NH_2$, followed by reaction with the electrophile $R^{31}N=C=O$, $R^{32}R^{31}N-C(O)-L$, $R^{31}-C(O)-L$, $R^{30}-SO_2-L$, $R^{32}R^{31}N-SO_2-L$, and the like, to prepare sulfonamide (10b).

30

SCHEME III

Alternatively, hydroxy amino acid (7) may be converted with nucleophiles, electrophiles and the like as described above or under Mitsunobu conditions to yield the amino acid intermediate (12) (Scheme III).

- 5 The amino acid intermediate (12) may subsequently be cyclised, sulfonylated and converted to hydroxamic acids using the aforementioned procedures to give hydroxamic acid (11).

- Alternatively, sulfonamides (10a) or (10b) (when R⁹ is H) may be halogenated, such as iodinated, and then carbonylated (See for example Schoenberg, A., et al, J.Org.Chem., 39, 3318, (1974)) and subsequently derivatised, amidated (See for example Corey, E.J. and Hegedus, L.S., J.Am.Chem.Soc., 91, 1233 (1969)),
 10 arylated or alkylated (See for example Stille, J.K., Angew. Int. Ed. Engl., 25, 508 (1986)) to yield sulfonamides (10a) or (10b) where R⁹ is other than H.

SCHEME IV

A second general synthesis useful for the preparation of the novel compounds of this invention is illustrated in Scheme IV whereby an appropriately

substituted heterocycle (13) or (14) is cyclized into bicyclic intermediate (15) in the presence of a base, such as KOH in THF, potassium carbonate in DMF, and the like, where L^a and L^b are each a leaving group, such as chloro, bromo, iodo, mesylate, tosylate and the like, or -V- L^a is an appropriately substituted ketone or aldehyde group, or -V- L^a or -W- L^b is an appropriately substituted unsaturated aldehyde, ketone, ester, amide, nitrile or the like Michael reaction acceptor, or other cyclization method well known to those skilled in the art.

Alternatively, the bicyclic intermediate (15) can be prepared in two steps from a protected amino acid (16) wherein the R^1 -SO₂- group is introduced after

cyclization with the amino group (-NH₂) (see Scheme V).

When appropriate R^8 , R^9 , R^{10} , R^{11} , R^{12} , R^{15} , R^{16} , R^{17} and R^{18} may be introduced prior to or after the cyclization step provided the radicals do not interfere with, compete with or inhibit the cyclization reaction. One skilled in the art is well versed in such matters and knows when and how to introduce the various groups and utilize protecting groups to prevent such deleterious effects.

SCHEME V

25

The intermediates (13), (14) and (16) are readily prepared from commercially available starting materials, for example as shown in Scheme VI, wherein P¹ and P² are protecting groups, L^a and L^b are leaving groups, A¹ is a radical that can be converted into -W- L^b and A² is a radical that can be converted into -V- L^a .

30

A third general synthesis useful for the preparation of the novel compounds of this invention is cyclization reactions, such as Friedel-Crafts and the like reactions, directly onto the heterocyclic ring as illustrated in Scheme VII, whereby an appropriately substituted heterocycle (17) or (18) is cyclized into bicyclic intermediate (15) by nucleophilic displacement of the leaving group L^a or L^b , such as in the presence of acid or a Friedel-Crafts reagent, such as tin chloride, aluminum chloride and the like, or other nucleophilic reaction conditions, such as formation of an anion on the ring, for example, metal halogen exchange and the like. (For an example of Friedel Crafts reaction, see Frehel, D, Badorc, A., Pereillo, J-M, Maffrand, J-P J Heterocycl Chem 1985, 22, 1011-1016) In such reactions, $-W-L^b$ and $-V-L^a$ are groups containing an electrophilic group, such as halogen (Cl, Br, I), ester, carboxylic acid, carboxylic acid halide, aldehyde, ketone, nitrile and the like.

SCHEME VI

Heterocycle (17) can be prepared from the sulfonamide (19) by reaction with L^b-W-L^c or A^1-L^c wherein A^1 is a radical that can be converted into $-W-L^b$ and wherein L^c is a leaving group similar to L^a and L^b . Sulfonamide (19) can be readily prepared from the corresponding protected or unprotected amino acid by reaction with the appropriate sulfonyl chloride (R^1-SO_2-Cl) or the like. The amino acid is either commercially available or is readily prepared from commercially available starting materials using methods well known to those skilled in the art.

SCHEME VII

Heterocycle (18) can be prepared by coupling the electrophile (20) with the sulfonamide (21) in the presence of a base, such as potassium carbonate and the like. The radical A^2 may be used in place of $-V-L^a$ in sulfonamide (21) to avoid reaction of $-V-L^a$ with the sulfonamide group, in which event A^2 is converted into $-V-L^a$ after reaction of the electrophile (20) with the sulfonamide (21). Electrophiles (20) are either commercially available or is readily prepared from commercially available starting materials using

methods well known to those skilled in the art. Sulfonamide (21) can be prepared from the corresponding protected or unprotected amino acid by reaction with the appropriate sulfonyl chloride (R^1 -

5 SO_2-Cl) or the like. The amino acid is either commercially available or is readily prepared from commercially available starting materials using methods well known to those skilled in the art.

Alternatively, protected or unprotected sulfonamide
10 intermediate (22), wherein R^b is R^{11} or a group which can be converted into R^{11} during the synthesis of the compounds of this invention, may be prepared from a substituted protected carboxylic acid intermediate (23) (Scheme VIII). The carboxylic acid intermediate (23)
15 can be selectively reduced to an aldehyde using appropriate reducing agents, such as DIBAL-H and the like, which is converted into the sulfonamide imine (24) by reaction of the aldehyde with the sulfonamide $R^1SO_2NH_2$ using reaction conditions well known in the art.

20 The sulfonamide imine (24) can then be reacted with a carbon nucleophile which can be converted into a carboxylic acid or ester, such as cyanide anion followed by hydrolysis, 1,3-dithiane anion followed by deprotection and oxidation, and the like, to yield the
25 protected or unprotected sulfonamide intermediate (22).

The substituted protected carboxylic acid intermediate (23) is commercially available or may be readily prepared from commercially available starting materials using methods well known to those skilled in
30 the art. For instance, Perkin condensation between heterocyclic acetic acids and aldehydes to give an unsaturated acid followed by hydrogenation, Michael reaction, allylic rearrangement and the like, aldol condensation, alkylation and the like can be used to
35 produce intermediate (23) from readily available

SCHEME VIII

5

SCHEME IX

starting materials. Alternatively, unsubstituted (i.e.,
 10 $\text{R}^b = \text{H}$) protected or unprotected carboxylic acid

intermediate (23) may be alkylated with electrophiles such as R^b-L , wherein L is a leaving group such as halogen, mesylate, tosylate, etc.

5

SCHEME X

For example, as shown in Scheme IX, an appropriately 3,4-substituted thiophene carboxaldehyde (25), wherein P_2 is a hydroxy protecting group, may be condensed, under basic conditions (for example in the presence of LDA in THF) with a protected N-sulphonylated glycine (26), wherein P_1 is a carboxylic acid protecting group such as an ester and the like, to give beta-hydroxy amino acid (27) (see for example Dikshit, D.K., et al. Tet. Lett. 1988, 29(25), 3109-3110). The beta-hydroxy amino acid (27) may then be protected with a hydroxy protecting group P_3 , such as by acylation of the beta-hydroxy group and separated into threo and erythro diastereomers. P_2 may then be removed and Mitsunobu cyclization conditions can give intermediate (28). P_1 may then be removed, a hydroxamic acid formed and P_3 removed to give (29a) utilizing methodology familiar to one skilled in the art. Alternatively, (28) may be deprotected to the

beta-hydroxy acid and converted to beta-carbamoyl hydroxamate (29b) or other substituted oxy group (i.e., $-OR^{20}$) compound (29c) again utilizing methodology familiar to one skilled in the art. This
5 general scheme is also applicable for other substituted heterocyclic carboxaldehydes as shown in Scheme X to form six, seven and eight membered heterocyclic fused compounds (I) of this invention.

Scheme XI illustrates an alternative general
10 synthesis (Claisen ring contraction) useful for the preparation of the novel compounds of this invention as illustrated in Scheme IV whereby an appropriately substituted heterocycle (14) is cyclized into bicyclic intermediate (15). As shown in Scheme XI, heterocycle
15 (31) can be prepared by coupling electrophile (30), wherein R^e is $-(CH_2)_m-L^a$ ($m = 0-1$) or a group which can be converted into $-(CH_2)_m-L^a$ and wherein R^f is W or a group which can be converted into W during the synthesis of the compounds of this invention, with the protected N-sulphonylated glycine (26), wherein P_1 is a carboxylic
20 acid protecting group such as an ester and the like, (for example, a Mitsunobu coupling, Syn. 1981:1-28). When R^e is a leaving group, such as bromine atom, R^e can be converted into $-(CH_2)_m-L^a$ by a homologation sequence
25 (for example, for $m = 1$ and $L^a = Br$, Palladium catalyzed Stille coupling of tributylvinyltin with the heterocycle (31) ($R^e = Br$), followed by oxidative cleavage (OsO_4 , $NaIO_4$) of the resulting vinyl group to form an aldehyde group ($R^e = -CHO$), reduction with $NaBH_4$ to an alcohol
30 group ($R^e = -CH_2OH$), and finally bromination of the alcohol (NBS and PPh_3) to form the desired heterocycle (32) ($m = 1$, $L^a = Br$)).

The Z-allylic alcohol (33) can be prepared by coupling (Z)- $Bu_3SnCH=CHCH_2OTBS$, which has been
35 synthesized and utilized in both its protected and unprotected forms (Corey et al., Tet. Lett. 25:2419-2422 (1984); Jung et al., Tet. Lett. 23:3851-3854 (1982); and

Stille et al., J. Am. Chem. Soc. 109:813-817 (1987)), with heterocycle (32). The coupling can be performed utilizing $\text{PdCl}_2(\text{PPh}_3)_2$ catalyzed Stille reaction (Stille, Chem. Int. Ed. Engl. 25:508-524 (1986); and Stille et al., J. Am. Chem. Soc. 101:4992-4998 (1979)).

Alternatively, (Z)- $\text{Bu}_3\text{SnCH}=\text{CHCH}_2\text{OTBDMS}$ (prepared from commercially available ethyl cis-3-iodoarylate by reduction with about two equivalents of DIBAL-H (Beruben et al., J. Org. chem. 60:2488-2501 (1995)) by slow addition at about -78°C to minimize double bond isomerization during the reaction followed by gradual warming to ambient temperature, the resulting iodo-alcohol is protected as its TBDMS ether and then subjected to halogen-metal exchange (butyl lithium and tributyltin chloride, Pearson et al., J. Org. Chem. 59:5662-5671 (1994)) to give the desired (Z)- $\text{Bu}_3\text{SnCH}=\text{CHCH}_2\text{OTBDMS}$) is utilized in the coupling reaction. The Z-allylic alcohol (33) then results following deprotection of the carboxylic acid (such as with KOH in THF) and the TMS group (such as with acid) or the TBDMS group (such as with TBAF in THF).

The lactone (34) is then prepared from the Z-allylic alcohol (33). Many methods that are available to form medium to large lactones (Meng et al., "Topics in Current Chemistry, Ring Closure Methods in the Synthesis of Macrocyclic Natural Products," Springer-Verlag (Pub.), Vol. 161 (1991); and Nicolaou, Tetrahedron 33:683-710 (1977)). For example, the lactone (34) can be prepared from the Z-allylic alcohol (33) utilizing Mukaiyama's reagent (Mukaiyama et al., Chem. Lett. 1976:49-50; and Mukaiyama, Chem. Int. Ed. Engl. 18:707-721 (1979)) under high dilution conditions (Funk et al., J. Org. Chem. 49:4320-4322 (1984); Cooper et al., J. Chem. Soc., Chem. Commun., 1987:1220; and Cooper et al., Tet. Lett. 28:3031 (1987)).

SCHEME XI

Claisen ring contraction of the lactone (34) can be
 5 effected by treatment of the lactone with various
 combinations of reagents including TBDMSCl/LDA,
 TBDMSOTf/LHMDS and TBDMSOTf/KHMDS, such as in THF at
 about -78°C (Ireland et al., J. Am. Chem. Soc. 98:2868-
 2877 (1976)) followed by heating the reaction, for
 10 example to reflux, to give the Claisen product as a

protected carboxylic acid which can be deprotected, such as with , to yield the heterocycle carboxylic acid (35). Any silyl ester of the heterocycle carboxylic acid (35) produced in the reaction can be removed by treatment
5 with aqueous K_2CO_3 in THF-MeOH to give the free the heterocycle carboxylic acid (35).

The relative stereochemistry between the vinyl and carboxylic acid groups of the heterocycle carboxylic acid (35) may be cis (Abelman et al., J. Am. Chem. Soc.
10 104:4030-4032 (1982); Funk et al., Tetrahedron 42:2831-2845 (1986); and Corey et al., J. Am. Chem. Soc. 118:1229-1230 (1996)). The carboxylic acid group of the heterocycle carboxylic acid (35) or the corresponding ester can be epimerized, for example by treatment with
15 base, and the resulting cis and trans diastereomers can be separated and the R and S enantiomers can be separated using methods well known to those skilled in the art. The 2-trimethylsilylethyl protecting group can be removed from the carboxylic acid group without
20 substantial epimerization from the cis stereochemistry with fluoride in the presence of DMAP. The hydroxamic acids (I) of this invention can then be prepared from the heterocycle carboxylic acid (35) using PyBroP, $NH_2OH \cdot HCl$ and Hunigs base in CH_2Cl_2 .

25 The alkene group of the heterocycle carboxylic acid (35) can be functionalize using methods well known in the art to produce a variety of groups. A recent methodology described by Suzuki et al. (Chem. Rev. 95:2457-2483 (1995)), which involves palladium catalyzed
30 coupling of alkylborane derivatives with alkenyl or aryl halides or triflates. For example, coupling of the hydroboration product of an ester of heterocycle carboxylic acid (35) with iodobenzene can yield heterocycles substituted with a phenethyl group. This
35 functionalization can be carried out in one pot by hydroboration with 9-BBN in THF, to give a terminally

substituted alkyl borane that is then treated with iodobenzene, K_2CO_3 and catalytic $PdCl_2(dppf)$.

It is apparent from the above description that no single general synthesis can be used in the preparation of all of the novel compounds of this invention, because some of the radicals, well known to those skilled in the art, will or may have the potential of interfering with, competing with or inhibiting the some of the reactions involved in the pathway. However, one skilled in the art is fully aware of appropriate point in the synthetic pathway when a radical may be introduced and when protecting groups can be used.

Sulfonyl halides can be prepared by the reaction of a suitable alkyl, aryl, heteroaryl, heterocyclyl and the like Grignard or lithium reagents with sulfuryl chloride, or sulfur dioxide followed by oxidation with a halogen, preferably chlorine. Alkyl, heteroaryl, heterocyclyl, aryl and the like Grignard or lithium reagents can be prepared from their corresponding halide (such as chloro or bromo) compounds which are commercially available or readily prepared from commercially available starting materials using known methods in the art. Alternatively, mercaptans may be oxidized to sulfonyl chlorides using chlorine in the presence of water under carefully controlled conditions. Additionally, sulfonic acids may be converted into sulfonyl halides using reagents such as PCl_5 , $SOCl_2$, $ClC(O)C(O)Cl$ and the like, and also to anhydrides using suitable dehydrating reagents. The sulfonic acids are either commercially available or may be prepared using procedures well known in the art from commercially available starting materials. In place of the sulfonyl halides, sulfinyl halides or sulfenyl halides can be utilized to prepare compounds wherein the sulfonyl moiety is replaced by an sulfinyl or thio moiety, respectively. Arylsulfonic acids, benzo fused heterocyclyl sulfonic acids or heteroaryl sulfonic acids

can be prepared by sulfonation of the aromatic ring by well known methods in the art, such as by reaction with sulfuric acid, SO_3 , SO_3 complexes, such as $\text{DMF}(\text{SO}_3)$, pyridine(SO_3), N,N-dimethylacetamide(SO_3), and the like.

- 5 Preferably, such sulfonyl halides are prepared from such aromatic compounds by reaction with $\text{DMF}(\text{SO}_3)$ and SOCl_2 or $\text{ClC}(\text{O})\text{C}(\text{O})\text{Cl}$. The reactions may be performed stepwise or in a single pot.

- Alkyl sulfonic acids, aryl sulfonic acids,
10 heterocyclyl sulfonic acids, heteroaryl sulfonic acids, alkylmercaptans, arylmercaptans, heterocyclylmercaptans, heteroarylmercaptans, alkylhalides, arylhalides, heterocyclylhalides, heteroarylhalides, and the like are commercially available or can be readily prepared from
15 starting materials commercially available using standard methods well known in the art.

- Thioether derivatives can be converted into the corresponding sulfone or sulfoxide by oxidizing the thioether derivative with a suitable oxidation agent in
20 a suitable solvent. Suitable oxidation agents include, for example, hydrogen peroxide, sodium meta-perborate, oxone (potassium peroxy monosulfate), meta-chloroperoxybenzoic acid, periodic acid and the like, including mixtures thereof. Suitable solvents include
25 acetic acid (for sodium meta-perborate) and, for other peracids, ethers such as THF and dioxane, and acetonitrile, DMF and the like, including mixtures thereof.

- The chemical reactions described above are
30 generally disclosed in terms of their broadest application to the preparation of the compounds of this invention. Occasionally, the reactions may not be applicable as described to each compound included within the disclosed scope. The compounds for which this
35 occurs will be readily recognized by those skilled in the art. In all such cases, either the reactions can be successfully performed by conventional modifications

known to those skilled in the art, e.g., by appropriate protection of interfering groups, by changing to alternative conventional reagents, by routine modification of reaction conditions, and the like, or
5 other reactions disclosed herein or otherwise conventional, will be applicable to the preparation of the corresponding compounds of this invention. In all preparative methods, all starting materials are known or readily prepared from known starting materials.

10 Prodrugs of the compounds of this invention are also contemplated by this invention. A prodrug is an active or inactive compound that is modified chemically through in vivo physiological action, such as hydrolysis, metabolism and the like, into a compound of
15 this invention following administration of the prodrug to a patient. The suitability and techniques involved in making and using prodrugs are well known by those skilled in the art. For a general discussion of prodrugs involving esters see Svensson and Tunek Drug
20 Metabolism Reviews 165 (1988) and Bundgaard Design of Prodrugs, Elsevier (1985). Examples of a masked carboxylate anion include a variety of esters, such as alkyl (for example, methyl, ethyl), cycloalkyl (for example, cyclohexyl), aralkyl (for example, benzyl, p-methoxybenzyl), and alkylcarbonyloxyalkyl (for example,
25 pivaloyloxymethyl). Amines have been masked as arylcarbonyloxymethyl substituted derivatives which are cleaved by esterases in vivo releasing the free drug and formaldehyde (Bundgaard J. Med. Chem. 2503 (1989)).
30 Also, drugs containing an acidic NH group, such as imidazole, imide, indole and the like, have been masked with N-acyloxymethyl groups (Bundgaard Design of Prodrugs, Elsevier (1985)). Hydroxy groups have been masked as esters and ethers. EP 039,051 (Sloan and
35 Little, 4/11/81) discloses Mannich-base hydroxamic acid prodrugs, their preparation and use.

Without further elaboration, it is believed that one skilled in the art can, using the preceding description, utilize the present invention to its fullest extent. The following preferred specific
5 embodiments are, therefore, to be construed as merely illustrative, and not limitative of the remainder of the disclosure in any way whatsoever.

The following Examples illustrate the preparation of compounds of the present invention and intermediates
10 useful in preparing the compounds of the present invention.

The resulting suspension was cooled to 0°C. A solution of potassium hydroxide (87.9% purity, 277.6g, 4.35mol) in absolute ethanol (1.3L) was then added dropwise over 7.5 hours. During this time, the reaction became homogeneous and shortly after a precipitate formed. Upon complete addition of the ethanolic KOH solution, the reaction mixture was stirred for an additional 0.5 hours and placed in a freezer over night. The precipitated solid was collected via filtration and dissolved into water (1L). A sufficient volume of glacial acetic acid (about 230ml) was added to adjust the pH to 5.5. The resulting solution was cooled to induce the precipitation of the desired product. The solid was collected via filtration to give pure DL-cis

10 days, the precipitated product was collected via filtration. The pH of the filtrate was adjusted to 5.0-6.0 using 10N NaOH. The solid product was collected via filtration. The combined products were dried to give the desired product. The NMR (D₂O) spectrum was

Example 33

Preparation of 4-trans-Benzyl-6-(4-methoxyphenyl
 20 sulfonyl)-4,5,6,7-tetrahydro-thieno[2,3,-c]pyridine-5-
hydroxamic acid.

Step A: 3-Phenyl-2-thien-3-yl-acrylic acid

To a stirred solution of 3-thienylacetic acid (30 g, 211
 25 mmol) in 200 mL acetic anhydride was added triethyl
 amine (29.4 mL, 211 mmol) and benzaldehyde (34.2 mL, 336
 mmol). The reaction was heated to reflux for two hours
 under Argon with stirring. The reaction mixture was
 treated with 300 mL water and refluxed for 5 minutes,
 30 followed by cooling to room temperature and then
 submerging in an ice bath for 30 minutes. The solid
 precipitate was collected by filtration, washed with 600

mL of 50% aqueous acetic acid and 600 mL of water and dried overnight in a vacuum dessicator to afford 3-phenyl-2-thien-3-yl-acrylic acid as a pale tan solid and used directly in the next step: MS (M+H)+ 231, (M+NH4)+ 248. (Das et al., J. Med. Chem. 16(12):1361-1365, 1973)

Step B: 3-Phenyl-2-thien-3-yl-propionic acid

A suspension of 3-phenyl-2-thien-3-yl-acrylic acid (10.2 g, 44 mmol) in 200 mL of absolute ethanol in a Parr bottle was degassed by evacuation/purge with Argon before addition of Wilkinson's catalyst (1.07 g, 1.2 mmol). The reaction was hydrogenated in a Parr shaker apparatus with heating to 60-70°C under 50 psi of hydrogen for 20 hours. The solvent was removed by rotary evaporation, and the dark residue was dissolved in 400 mL of 1N sodium hydroxide and washed with 2 portions of 200 mL of ethyl acetate. The aqueous layer was acidified to pH 2 with 1N aqueous hydrochloric acid before extracting with 3 portions of 100 mL of ethyl acetate. The combined organic layers after acid treatment were dried with sodium sulfate, filtered, evaporated and dried in vacuo to afford 3-phenyl-2-thien-3-yl-propionic acid as a tan solid: MS (M-H)- 231

Step C: Methyl 3-Phenyl-2-thien-3-yl-propionate

To a solution of 3-phenyl-2-thien-3-yl-propionic acid (9 g, 38.7 mmol) in anhydrous methanol was slowly added thionyl chloride (1 mL, 13.7 mmol). The reaction was heated to reflux overnight, followed by removal of solvent under reduced pressure. The dark residue was diluted with ethyl acetate, washed with saturated aq sodium bicarbonate and brine. The organic phase was dried (sodium sulfate), filtered and evaporated to afford the methyl ester homogenous by TLC: MS (M+H)+ 247, (M+NH4)+ 264

Step D: 3-Phenyl-2-thiophen-3-yl-propionaldehyde

To a stirred cooled (-78°C) solution of methyl 3-phenyl-2-thien-3-yl-propionate (8.3 g, 33.73 mmol) in 65 mL anhydrous toluene under Argon was added a pre-cooled (-78°C) solution of diisobutylaluminum hydride (52.5 mL of a 1 M solution in toluene, 52.5 mmol) dropwise, via cannula, so the internal temperature of the reaction does not rise above -65°C. After 25 minutes at -78°C, TLC indicated complete consumption of methyl ester, and the reaction was quenched by careful addition of pre-cooled (-78°C) anhydrous methanol (32.6 mL) dropwise via cannula, so the internal temperature again does not rise above -65°C. After warming to ambient temperature overnight, the reaction was quenched by adding aqueous citric acid and extracted with ethyl acetate. The organic layer was washed with water, saturated aqueous sodium potassium tartrate, dried, filtered and evaporated to yield a crude product. The product was purified by silica gel flash chromatography using step gradient of hexanes/ethyl acetate 9:1; 8:1; 7:1; 3:1 to afford the aldehyde: MS (M+MeOH+NH₄)⁺ 266

Step E: 2-Hydroxy-4-phenyl-3-thien-3-yl-butyronitrile

The mixture was capped tightly before removing the ice bath and was stirred at room temperature overnight. The reaction was extracted with 4 portions of 50 mL of diethyl ether and 2 portions of 10 mL of ethyl acetate. The combined organic layers were dried (magnesium sulfate), filtered and evaporated to afford crude 2-hydroxy-4-phenyl-3-thien-3-yl-butyronitrile: MS (M+H)⁺ 243.

The mixture was cooled to room temperature, and treated with concentrated aq potassium hydroxide to pH 5-6. The reaction was extracted with several portions of ethyl acetate, the organic layers were dried, filtered and evaporated to yield crude 2-hydroxy-4-phenyl-3-thien-3-yl-butyric acid: MS (M-H)⁻ 261

The solvent was removed in vacuo, and the residue was dissolved in ethyl acetate and washed with saturated sodium bicarbonate, and water. The combined organic phases were dried (magnesium sulfate), filtered and evaporated to afford crude product. This was purified by flash chromatography on silica gel using gradient elution of hexanes/ethyl acetate 9:1 to 8:1 to afford (a) pure faster eluting diastereomer as a clear oil, (b) a mixture of diastereomers and (c) slower eluting diastereomer as pale yellow oil: MS (M+H)⁺ 277, (M+NH₄)⁺ 294

After the white solid complex precipitated, a solution of methyl 2-hydroxy-4-phenyl-3-thien-3-yl-butyrate (1.38 g, 5 mmol, faster eluting diastereomer) in 12 mL of tetrahydrofuran is added dropwise via cannula, followed by a solution of

N-(tert-butoxycarbonyl)-p-methoxybenzenesulfonamide (3.06 g, 10.6 mmol) in 20 mL THF. The yellow-orange reaction was warmed to ambient temperature and heated to 35°C for four days under an atmosphere of Argon until

Example 73

The following assays are in vitro assays which were used to characterize the ability of compounds of this invention to inhibit the production of TNF- α by monocytes following LPS stimulation, Human Monocyte TNF Convertase Assay, Human Neutrophil Collagenase Assay and Human Fibroblast Stromelysin Assay.

10 **Lipopolysaccharide-activated monocyte TNF production assay**

Isolation of monocytes

Test compounds were evaluated in vitro for the ability to inhibit the production of tumor necrosis factor (TNF) by monocytes activated with bacterial lipopolysaccharide (LPS). Fresh residual source leukocytes (a byproduct of plateletpheresis) were obtained from the local blood bank and peripheral blood mononuclear cells (PBMCs) were isolated by density gradient centrifugation on Ficol-Paque Plus (Pharmacia). PBMCs were suspended at 2×10^6 /ml in DMEM supplemented to contain 2% FCS (10 mM), 0.3 mg/ml glutamate, 100 U/ml penicillin G and 100 mg/ml streptomycin sulfate (complete media). Cells were plated into Falcon flatbottom 96 well culture plates (200 μ l/well) and cultured overnight at 37°C and 6% CO₂. Nonadherent cells were removed by washing with 200 μ l/well of fresh medium. Wells containing adherent cells (~70% monocytes) were replenished with 100 μ l of fresh medium.

30

Preparation of test compound stock solutions

Test compounds were dissolved in DMS. Compound stock solutions were prepared to an initial concentration of 10 - 50 μ M. Stocks were diluted initially to 20 - 200 μ M in complete media. Nine two-fold serial dilutions of each compound were then prepared in complete medium.

35

Treatment of cells with test compounds and activation of
TNF production with lipopolysaccharide

One hundred microliters of each test compound
5 dilution were added to microtiter wells containing
adherent monocytes and 100 μ l complete medium.
Monocytes were cultured with test compounds for 60 min
at which time 25 μ l of complete medium containing 30
ng/ml lipopolysaccharide from *E. coli* K532 were added to
10 each well. Cells were cultured an additional 4 hrs.
Culture supernatants were then removed and TNF present
in the supernatants was quantified using an ELISA.

TNF ELISA

15 Flat bottom 96 well Corning High Binding ELISA
plates were coated overnight (4°C) with 150 μ L/well of 3
 μ g/ml murine anti-human TNFa MAb (R&D Systems #MAB210).
Wells were then blocked 1 h at room temperature with 200
 μ L/well of CaCl₂-free ELISA buffer supplemented to
20 contain 20 mg/ml BSA (standard ELISA buffer: 20 mM, 150
mM NaCl, 2 mM CaCl₂, 0.15 mM thimerosal, pH 7.4).
Plates were washed and replenished with 100 μ l of test
supernatants (diluted 1:3) or standards. Standards
consisted of eleven 1.5-fold serial dilutions from a
25 stock of 1 ng/ml recombinant human TNF (R&D Systems).
Plates were incubated at room temperature for 1 h on
orbital shaker (300 rpm), washed and replenished with
100 μ l/well of 0.5 μ g/ml goat anti-human TNFa (R&D
systems #AB-210-NA) biotinylated at a 4:1 ratio. Plates
30 were incubate for 40 min, washed and replenished with
100 μ l/well of alkaline phosphatase-conjugated
streptavidin (Jackson ImmunoResearch #016-050-084) at
0.02 μ g/ml. Plates were incubated 30 min, washed and
replenished with 200 μ l/well of 1 mg/ml of p-nitrophenyl
35 phosphate. After 30 min, plates were read at 405 nm on
a Vmax plate reader.

Data analysis

Standard curve data were fit to a second order polynomial and unknown TNFa concentrations determined from their OD by solving this equation for concentration. TNF concentrations were then plotted vs. test compound concentration using a second order polynomial. This equation was then used to calculate the concentration of test compounds causing a 50% reduction in TNF production.

Human Monocyte TNF Convertase Assay

TNF convertase activity is demonstrated by hydrolytic cleavage of a dinitrophenyl (DNP)-labeled peptide substrate between amino acids Ala and Val. Dependent on the purity of the TNF convertase used in the reaction, hydrolysis of incorrectly clipped DNP-peptides are also possible. Human monocyte TNF convertase activity is determined by using DNP-labeled peptide substrate (1) Dnp-SPLAQAVRSSSR-CONH₂; and clipped peptides: (2) DNP-SPLAQ-COOH (incorrectly clipped between Gln and Ala); (3) DNP-SPLAQA-COOH (correctly clipped); and (4) DNP-SPLAQAV-COOH (incorrectly clipped between Val and Arg).

Full length and clipped DNP-peptides are separated and quantitated using reversed phase HPLC, monitoring at 350 nM (where dinitrophenyl absorbs). Inhibitors of TNF convertase in the reaction are detected by a decrease in peak height of peptide 3 and an increase in peak height of peptide 1. Inhibition is calculated as percent of control by comparing peak height of peptide 3 in samples with no inhibitors (control conditions) and peak height of peptide no. 3 in samples with inhibitors.

Typically, compounds at 2 mM in DMSO are first diluted 1:11.8 in 40 mM Tris, pH 7.5. A further 1:17 dilution of the compound occurs in the final reaction mixture. This reaction mixture contains 2.5µL of the

diluted compound, 20 μ L of peptide 1, and 20 μ L of TNF convertase. This results in a compound concentration of 10 μ M, 0.5% DMSO, in the final reaction volume. Compounds are initially screened at 10 μ M and selected compounds are
5 further assayed to determine an IC_{50} .

Human Neutrophil Collagenase Assay

Human neutrophil collagenase (HNC) activity is determined by using fluorogenic peptide substrate Dnp-
10 Pro-b-Cyclohexyl-Ala-Gly-Cys(Me)-His-Ala-Lys-(N-methylanthranilic acid)- NH_2 . The N-terminus Dnp group and the C-terminus N-methyl-anthranilyl moiety (Nma) are fluorescence self-quenching until the peptide is cleaved at the Gly-Cys(me) bond. The fluorescence from the
15 cleavage products is measured on a Bio-Tek Instrument FL500 fluorescence micro-plate reader (excitation at 360 nm, emission at 460 nm). The assay is performed in a 96-well plate (in duplicate), and the K_m = 51 nM for the substrate, and K_i = 722 nM for Actinonin have been
20 determined. The test compounds (at 100, 33 & 10 nM) are compared for their inhibition of HNC activity on the substrate against the activity of Actinonin and K_i 's were determined on selected compounds.

25 Human Fibroblast Stromelysin Assay

Human fibroblast stromelysin (HFS) activity is determined by using fluorogenic peptide substrate Dnp-
Pro-b-Cyclohexyl-Ala-Gly-Cys(Me)-His-Ala-Lys-(N-methylanthranilic acid)- NH_2 . The N-terminus Dnp group
30 and the C-terminus N-methyl-anthranilyl moiety (Nma) are fluorescence self-quenching until the peptide is cleaved at the Gly-Cys(me) bond. The fluorescence from the cleavage products is measured on a Bio-Tek Instrument FL500 fluorescence micro-plate reader (excitation at 360
35 nm, emission at 460 nm). The assay is performed in a 96-well plate (in duplicate), and the K_m = 51 nM for the substrate, and K_i = 722 nM for Actinonin (an inhibitor

of enzyme activity; Sigma Chemical, St. Louis, MO; A6671) have been determined as the standard control. The test compounds (at 100, 33 & 10 mM) are compared for their inhibition of HFS activity on the substrate against the activity of Actinonin and Ki's were determined on selected compounds.

Inhibition of LPS-Induced TNF- α production in mice

Male DBA/1LACJ mice were dosed with vehicle or test compounds in a vehicle (the vehicle consisting of 0.5% tragacanth in 0.03 N HCl) prior to lipopolysaccharide (2 mg/kg, I.V.) injection. Ninety minutes after LPS injection, blood was collected and the serum was analyzed by ELISA for TNF levels.

The following compounds had a TNF convertase, HNC and/or HFS inhibition activity IC₅₀ of less than 1 μ M:

This invention also relates to a pharmaceutical
composition comprising a compound of this invention and
25 a pharmaceutically acceptable carrier, and if desired
other active ingredients. The compounds of this
invention are administered by any suitable route,
preferably in the form of a pharmaceutical composition
adapted to such a route, and in a dose effective for the
30 treatment intended. Therapeutically effective doses of
the compounds of the present invention required to
arrest the progress or prevent tissue damage associated
with the disease are readily ascertained by one of
ordinary skill in the art.

35 For the prophylaxis and treatment of disease
states, the compounds of the present invention may be
administered orally, parentally, or by inhalation spray,

rectally, or topically in dosage unit formulations containing conventional pharmaceutically acceptable carriers, adjuvants and vehicles. The term parenteral as used herein includes, subcutaneous, intravenous, 5 intramuscular, intrasternal, infusion techniques or intraperitoneally.

The amount of active ingredient that may be combined with the carrier materials to produce a single dosage form will vary depending upon the host treated 10 and the particular mode of administration.

The dosage regimen for treating a disease state with the compounds of this invention and/or compositions of this invention is based on a variety of factors, including the type of disease, the age, weight, sex and 15 medical condition of the patient, the severity of the condition, the route of administration, pharmacological considerations such as the activity, efficacy, pharmacokinetic and toxicology profiles of the particular compound employed, whether a drug delivery 20 system is utilized and whether the compound is administered as part of a drug combination. Thus the dosage regimen may vary widely. Dosage levels of the order from about 0.01 mg to 80 mg per kilogram of body weight per day, preferably from about 0.5 mg to 30 25 mg/kg, more preferably from about 1 mg to 15 mg/kg are useful for all methods of use disclosed herein. The pharmaceutically active compounds of this invention can be processed in accordance with conventional methods of pharmacy to produce medicinal agents for administration 30 to patients, mammals including humans.

For oral administration, the pharmaceutical composition may be in the form of, for example, a capsule, a tablet, a suspension, or liquid. The pharmaceutical composition is preferably made in the 35 form of a dosage unit containing a given amount of the active ingredient. For example, these may contain an amount of active ingredient from about 1 to 250 mg,

preferably from about 25 to 150 mg. A suitable daily dose for a human or other mammal may vary widely depending on the condition of the patient and other factors.

5 The compounds of this invention may also be administered by injection as a composition with suitable carriers including saline, dextrose, or water. The daily parenteral dosage regimen will be from about 0.1 to about 80 mg/kg of total body weight, preferably from
10 about 0.5 to about 30 mg/kg, and more preferably from about 1 mg to 15 mg/kg.

Injectable preparations, for example, sterile injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable
15 dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a nontoxic parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable
20 vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be
25 employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

Suppositories for rectal administration of the drug can be prepared by mixing the drug with a suitable
30 nonirritating excipient such as cocoa butter and polyethylene glycols which are solid at ordinary temperatures but liquid at the rectal temperature and will therefore melt in the rectum and release the drug.

A suitable topical dose of compounds of this
35 invention is 0.1 mg to 150 mg administered one to four, preferably two or three times daily. For topical administration, the active ingredient may comprise from

0.001% to 10% w/w, e.g. from 1% to 2% by weight of the formulation, although it may comprise as much as 10% w/w, but preferably not more than 5% w/w, and more preferably from 0.1% to 1% of the formulation.

5 Formulations suitable for topical administration include liquid or semi-liquid preparations suitable for penetration through the skin such as liniments, lotions, ointments, creams, or pastes and drops suitable for administration to the eye, ear, or nose.

10 For administration, the compounds of this invention are ordinarily combined with one or more adjuvants appropriate for the indicated route of administration. The compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanolic acids,
15 stearic acid, talc, magnesium stearate, sodium, magnesium oxide, sodium and calcium salts of phosphoric and sulphuric acids, acacia, gelatin, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, and tableted or encapsulated for conventional
20 administration. Alternatively, the compounds of this invention may be dissolved in saline, water, polyethylene glycol, propylene glycol, ethanol, corn oil, peanut oil, cottonseed oil, sesame oil, benzyl alcohol, and/or various buffers. Other adjuvants and
25 modes of administration are well known in the pharmaceutical art. The carrier or diluent may include time delay material, such as glyceryl monostearate or glyceryl distearate alone or with a wax, or other materials well known in the art.

30 The pharmaceutical compositions may be made up in a solid form including granules, powders or suppositories or in a liquid form such as solutions, suspensions, or emulsions. The pharmaceutical compositions may be subjected to conventional pharmaceutical operations such
35 as sterilization and/or may contain conventional adjuvants, such as preservatives, stabilizers, wetting agents, emulsifiers, buffers, etc.

Solid dosage forms for oral administration may include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound may be admixed with at least one inert diluent such as sucrose
5 lactose or starch. Such dosage forms may also comprise, as in normal practice, additional substances other than inert diluents, e.g., lubricating agents such as magnesium stearate. In the case of capsules, tablets, and pills, the dosage forms may also comprise buffering
10 agents. Tablets and pills can additionally be prepared with enteric coatings.

Liquid dosage forms for oral administration may include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs containing
15 inert diluents commonly used in the art, such as water. Such compositions may also comprise adjuvants, such as wetting agents, emulsifying and suspending agents, and sweetening, flavoring, and perfuming agents.

Compounds of the present invention can possess one
20 or more asymmetric carbon atoms and are thus capable of existing in the form of optical isomers as well as in the form of racemic or nonracemic mixtures thereof. The optical isomers can be obtained by resolution of the racemic mixtures according to conventional processes,
25 for example by formation of diastereoisomeric salts by treatment with an optically active acid or base. Examples of appropriate acids are tartaric, diacetyltartaric, dibenzoyltartaric, ditoluoyltartaric and camphorsulfonic acid and then separation of the
30 mixture of diastereoisomers by crystallization followed by liberation of the optically active bases from these salts. A different process for separation of optical isomers involves the use of a chiral chromatography column optimally chosen to maximize the separation of
35 the enantiomers. Still another available method involves synthesis of covalent diastereoisomeric molecules by reacting compounds of Formula I with an

optically pure acid in an activated form or an optically pure isocyanate. The synthesized diastereoisomers can be separated by conventional means such as chromatography, distillation, crystallization or sublimation, and then hydrolyzed to deliver the enantiomerically pure compound. The optically active compounds of Formula I can likewise be obtained by utilizing optically active starting materials. These isomers may be in the form of a free acid, a free base, an ester or a salt.

The compounds of the present invention can be used in the form of salts derived from inorganic or organic acids. These salts include but are not limited to the following: acetate, adipate, alginate, citrate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, camphorate, camphorsulfonate, digluconate, cyclopentanepropionate, dodecylsulfate, ethanesulfonate, glucoheptanoate, glycerophosphate, hemisulfate, heptanoate, hexanoate, fumarate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxy-ethanesulfonate, lactate, maleate, methanesulfonate, nicotinate, 2-naphthalenesulfonate, oxalate, palmoate, pectinate, persulfate, 3-phenylpropionate, picrate, pivalate, propionate, succinate, tartrate, thiocyanate, tosylate, mesylate and undecanoate. Also, the basic nitrogen-containing groups can be quaternized with such agents as lower alkyl halides, such as methyl, ethyl, propyl, and butyl chloride, bromides, and iodides; dialkyl sulfates like dimethyl, diethyl, dibutyl, and diamyl sulfates, long chain halides such as decyl, lauryl, myristyl and stearyl chlorides, bromides and iodides, aralkyl halides like benzyl and phenethyl bromides, and others. Water or oil-soluble or dispersible products are thereby obtained.

Examples of acids which may be employed to form pharmaceutically acceptable acid addition salts include such inorganic acids as hydrochloric acid, sulphuric

acid and phosphoric acid and such organic acids as oxalic acid, maleic acid, succinic acid and citric acid. Other examples include salts with alkali metals or alkaline earth metals, such as sodium, potassium, calcium or magnesium or with organic bases.

While the compounds of the invention can be administered as the sole active pharmaceutical agent, they can also be used in combination with one or more other agents. When administered as a combination, the therapeutic agents can be formulated as separate compositions which are given at the same time or different times, or the therapeutic agents can be given as a single composition.

The foregoing is merely illustrative of the invention and is not intended to limit the invention to the disclosed compounds. Variations and changes which are obvious to one skilled in the art are intended to be within the scope and nature of the invention which are defined in the appended claims.

From the foregoing description, one skilled in the art can easily ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions.

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 98/ 16147

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 46 to 60
because they relate to subject matter not required to be searched by this Authority, namely:
Remark: Although claims 46 to 60
are directed to a method of treatment of the human/animal
body, the search has been carried out and based on the alleged
effects of the compound/composition.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such
an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all
searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment
of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report
covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is
restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
